

A Novel Approach to Parameterized Verification

Yongjian Li Kaiqiang Duan Shaowei Cai Yi Lv

Abstract—Parameterized verification of parameterized protocols like cache coherence protocols is important but hard. Our tool paraVerifier handles this hard problem in a unified framework: (1) it automatically discovers auxiliary invariants and the corresponding causal relations from a small reference instance of the verified protocol; (2) the above invariants and causal relation information are automatically generalized into a parameterized form to construct a parameterized formal proof in a theorem prover (e.g., Isabelle). The principle underlying the generalization is the symmetry mapping. Our method is successfully applied to typical benchmarks including snoopy-based and directory-based benchmarks. Another novel feature of our method lies in that the final verification result of a protocol is provided by a formal and readable proof.

I. INTRODUCTION

Verification of parameterized concurrent systems is interesting in the area of formal methods, mainly due to the practical importance of such systems. Parameterized systems exist in many important application areas, including cache coherence, security, and network communication protocols. The hardness of parameterized verification is mainly due to the requirement of correctness that the desired properties should hold in any instance of the parameterized system. The model checkers, although powerful in verification of non-parameterized systems, become impractical to verify parameterized systems, as they can verify only an instance of the parameterized system in each execution. A desirable approach is to provide a proof that the correctness holds for any instance.

Related Work: There have been a lot of studies in the field of parameterized verification [1], [2], [3], [4], [5], [6], [7], [8], [9]. Among them, the ‘invisible invariants’ method [3] is an automatic technique for parameterized verification. In this method, auxiliary invariants are computed in a finite system instance to aid inductive invariant checking. Combining parameter abstraction and guard strengthening with the idea of computing invariants in a finite instance, Lv et al. [8] use a small instance of a parameterized protocol as a ‘reference instance’ to compute candidate invariants. References to a specific node in these candidate invariants are then abstracted away, and the resulting formulas are used to strengthen guards of the transition rules in the abstract node. Both works [3], [8] attempt to automatically find invariants. However, the invisible invariants are raw boolean formulas transferred from the reachable state set of a small finite instance of a protocol, which are BDDs computed by TLV (an variant of BDD-based SMV model checker). They are too raw to have an intuitive meanings. The capacity of the invisible invariant method is seriously limited when computing the reachable set of invisible invariants for the inductive checking is not feasible in the case of a large example like FLASH. Until now, the examples, which can be handled by the “invisible invariant” method, are

quite small, we still can’t find successful experiments on large examples like FLASH.

The CMP method, which adopts parameter abstraction and guard strengthening, is proposed in [6] for verifying a safety property inv of a parameterized system. An abstract instance of the parameterized protocol, which consists of $m + 1$ nodes $\{P_1, \dots, P_m, P^*\}$ with m normal nodes and one abstract node P^* , is constructed iteratively. The abstract system is an abstraction for any protocol instance whose size is greater than m . Normally the initial abstract system does not satisfy the invariant inv . Nevertheless it is still submitted to a model checker for verification. When a counterexample is produced, one needs to carefully analyze it and comes up with an auxiliary invariant inv' , then uses it to strengthen the guards of some transition rules of the abstract node. The ‘strengthened’ system is then subject to model checking again. This process stops until the refined abstract system eventually satisfies the original invariant as well as all the auxiliary invariants supplied by the user. However, this method’s soundness is only argued in an informal way. To the best of our knowledge, no one has formally proved its correctness in a theorem prover. This situation may be not ideal because its application domain for cache coherence protocols which demands the highest assurance for correctness. Besides, the analysis of counter-example and generation of new auxiliary invariants usually depend on human’s deep insightful understanding of the protocol. It is too laborious for people to do these analysis and some effective automatic tool is needed to help people.

Predicate abstraction is also applied to the verification of parameterized systems. Baukus, Lakhnech, and Stahl have used it to verify German (without data paths)[?], and Das, Dill, and Park have used it to verify FLASH[10]. The core of predicate abstraction is to discover a set of predicates, which are needed to abstract the states of a system, and an abstract state is a valuation of the predicates. Unfortunately, the task of discover proper predicates is neither easy nor automatic. Furthermore, the abstracted system is needed to proved to be conservative for certain properties under verification. This proof also needs a set of auxiliary invariants. Therefore searching enough auxiliary invariants can’t be avoided. No further efforts are made to make automatic both the discovery of proper predicates and the searching of auxiliary invariants in the work of applying predicate abstraction to the parameterized verification.

Sylvain Conchon, Amit Goel, Sava Krstic, Alain Mebsout, and Fatiha Zaidi have made progress in searching automatically auxiliary invariants[13]. A heuristics-guided algorithm, called Barb, searches auxiliary invariants backward with the help of an oracle (a reference instance of the protocol). Roughly speaking, Barb’s work can be seen as a backward

reachability analysis. Barb is implemented in an SMT-based model checker Cubicle[?]. The correctness of Barb is argued in a generic symbolic framework. The searched auxiliary invariants are claimed to be inductive for deductive proof in a case study of a protocol. However, the formulation of Barb and the proof is not done in a theorem prover. Neither is a formal proof is given adopting the invariants for the protocol. Besides, the configuration of oracle need to be done manually.

The degree of rigorousness and automation are two critical aspects of approaches to parameterized verification. The verification of real-world parameterized systems is, however, rarely both rigorous and automatic. For instance, FLASH protocol is the cache coherence protocol of the Stanford FLASH mutlitprocessor [?]. This protocol is so complex that only a few approaches [10], [11], [6], [13] have successfully verified it so far. Furthermore, all existing successful verification approaches have their downsides. [10] is a theorem proving based approach which requires to construct inductive invariants by hand. The cases of [11] and [6] are similar to [10] that hand-crafted invariants are required to provide by human experts. As a contrast, [13] is a model checking based approach which can be carried out automatically. However, the formal proof can not be obtained from the work of [13]. In order to effectively verify complex parameterized protocols like FLASH protocol, there are two issues need to be addressed. The first one is how to find a set of sufficient and necessary invariants without (or with less) human intervention, which is a core research topic in this field. The second one is the rigorousness of the verification. It is preferable to formulate all the verification in a publicly-recognized trust-worthy framework like a theorem prover [6].

It is not difficult to formalize the model and properties of a protocol in a theorem prover like Isabelle, however, it is too hard to construct a proof. Because the most creative choices in a formal proof are done by human and hard to be automated. These choices mainly lie in: (1) the induction scheme; (2) the case analysis: different subproofs are done in different cases. (3) the quantifier instantiations. Up to now, the main efforts are made in searching invariants automatically. Few people have considered how to link the invariant searching with proof checking. The invariants found automatically from a concrete instance of the protocol in [3], [13], [8] without consideration how to use them in a theorem proving, thus, it is still hard to automate the above three kinds of intelligent choices. In detail, the invariants and rules are usually in concrete form in the procedure of invariant searching, but not in a parameterized form which are required in theorem proving. The generalization from a result obtained in the concrete protocol instance to that in the parameterized instance is not fully considered. Therefore, much human intervention is still needed. The complexity of parameterized verification is usually beyond huamn's power. This is the reason why a theorem prover is still selodmly used in parameterized verification.

In order to solve the parameterized verification in a both automatical and rigorous way, we must consider the invariant searching with proof checking in a unified framework. The

key ideas are to make the aforementioned generalization automatically and to make the aforementioned creative choices in theorem proving to be automated. In detail,

- 1) We propose a special induction scheme for parameterized verification. Three kinds of causal relations among a formula and a rule and a set of formulas are introduced, which are essentially special cases of the general induction rule. Notably, with proper case analysis on the comparing parameters of a parameterized rule and those of a parameterized form, the three special induction proof rules can be applied automatically in a theorem prover.
- 2) A so-called consistent relation among a protocol instance and a set of formulas is proposed basing on the above three causal relations, which is the cornerstone in our method. If such a consistent relation holds, then any formula in the formula set is an invariant for the protocol instance. Here the protocol instance can be either concrete or parameterized.
- 3) From an initially given invariant, our tool search both invariants and causal relations from a small concrete protocol instance which can construct a consistent relation between the protocol instance and the set of all found invariants. Notice that both invariants and causal relations, which are searched in this phase, are concrete and stored in a table.
- 4) Basing on the analysis and generalization by comparing the parameters of a concrete rule and those of a concrete invariant occurring in a line of the table, we generalize the line into a symbolic form. Namely, the invariants and rules will be generalized into symbolic forms, and a symbolic formula is generated basing on the above analysis of concrete parameters, and used to indicate the case condition in which the comparison should be satisfied between the symbolic parameters of the symbolic invariants and rules. Thus, the information on the splitting cases decided by comparison between the two symbolic parameters of a parameterized rule and a parameterized invariant formula is given in the generalized table. The choice of the three special induction proof rules in each case is also given in a line.
- 5) From the table in 4, a formal proof script in a theorem prover (e.g., Isabelle) can be generated to prove that a consistent relation also holds between the parameterized protocol instance and the set of the parameterized invariant formulas. Notably, because the proof script has enough proof commands to do induction, and case analysis and necessary quantifier instantiation, the proof script can be automatically checked once it is fed into the theorem prover.

Basing on the above ideals, We design a tool called **paraVerifier**, which is shown as below:

Fig. 1. The workflow of paraVerifier

Our tool **paraVerifier** is composed of two parts: an invariant finder **invFinder** and a proof generator **proofGen**. Given a protocol \mathcal{P} and a property inv , **invFinder** tries to find useful auxiliary invariants and causal relations which are capable of proving inv . To construct auxiliary invariants and causal relations, we employ heuristics inspired by consistency relation. Also, when several candidate invariants are obtained using the heuristics, we use oracles such as a model checker and an SMT-solver to check each of them under a small reference model of \mathcal{P} , and chooses the one that has been verified.

After **invFinder** finds the auxiliary invariants and causal relations, **proofGen** generalizes them into a parameterized form, which are then used to construct a completely parameterized formal proof in a theorem prover (e.g., Isabelle) to model \mathcal{P} and to prove the property inv . The generated proof is checked automatically.

The organization of this work is as follows: Section II introduces the preliminaries; Section III introduces the theoretical foundation; Section IV the **invFinder**; Section V the generalization strategy; Section VI the **proofGen** and the generated proof. We go through these sections by verifying a small example - mutual exclusion example. Section VII shows the further experiments on real-world protocols. Section VIII concludes our work.

II. PRELIMINARIES

In this section, we introduce the theoretical foundation underlining **paraVerifier**. Consider a set of state variables V , we use e , f and S to denote an expression, a formula, and a statement over the set of state variables V . Variables are divided into two classes: array variables or non-array (global) variables. Basing on the variables, first order expressions and formulas can be defined as usual. We also assume that the variables in V range over a finite set D . A state s of a protocol is an instantaneous snapshot of its behavior given by a mapping from all variables in V to D . We write $\mathbb{A}[e, s]$ (and $s \models f$) to denote the evaluation result of the expression and (and formula f is evaluated to be true) at the state s . With a parallel assignment $S = \{x_i := e_i \mid i > 0\}$, we define the notion of the weakest precondition $\text{preCond}(S, f) \equiv f[x_i := e_i]$, which substitutes each occurrence of x_i by e_i .

Protocols. A cache coherence protocol is formalized as a pair (I, R) , where (1) I is an initialization formula; and (2) R is a set of transition rules. Each rule $r \in R$ is defined as $g \triangleright S$, where g is a predicate, and S is a parallel assignment to distinct variables v_i with expressions e_i . We write $\text{pre}(r) = g$, and $\text{act}(r) = S$ if $r = g \triangleright S$. A state transition is caused by trigger and execution of a rule, formally, we define: $s \xrightarrow{r} s' \equiv s \models \text{pre}(r) \wedge (\forall x \in \text{vars}(\text{act}(r)). s'(x) = \mathbb{A}[e, s] \wedge (\forall x \notin \text{vars}(\text{act}(r)). s'(x) = s(x))$.

Reachable state sets. As usual, the reachable state set of protocol $\mathcal{P} = (I, R)$, denoted as $\text{reachableSet}(\mathcal{P})$, can be defined inductively: (1) a state s is in $\text{reachableSet}(\mathcal{P})$ if there exists a formula $f \in I$, and $s \models f$; (2) a state s is

in $\text{reachableSet}(\mathcal{P})$ if there exists a state s_0 and a rule $r \in R$ such that $s_0 \in \text{reachableSet}(\mathcal{P})$ and $s_0 \xrightarrow{r} s$.

Now we use a simple example to illustrate the above definitions by a simple mutual exclusion protocol with N nodes. Let $I(\text{dle})$, $T(\text{rying})$, $C(\text{ritical})$, and $E(\text{xiting})$ be enumerating values to indicate the state of a node, x , n are simple and array variables, N a natural number. x is a flag to indicate ? $\text{pini}(N)$ the predicate to specify the inial state, $\text{prules}(N)$ the four rules of the protocol, $\text{mutuallnv}(i, j)$ a property that $n[i]$ and $n[j]$ cannot be in a critical state at the same time. We want to verify that $\text{mutuallnv}(i, j)$ holds at any reachable state for any $i \leq N, j \leq N$ s.t. $i \neq j$.

Example 1 Mutual-exclusion example.

```
pini(N) ≡ x=true ∧ ∧i=1N n[i]=I
try(i) ≡ n[i] = I ▷ n[i] := T
crit(i) ≡ n[i] = T ∧ x = true ▷ n[i] := C; x := false
exit(i) ≡ n[i] = C ▷ n[i] := E
idle(i) ≡ n[i] = E ▷ n[i] := I; x := true
prules(N) ≡ {r. ∃ i. i ≤ N ∧ ( r=crit(i) ∨ r=exit(i) )}
V r=idle(i) ∨ r=try(i)}
mutualEx(N) ≡ (pIni(N), prules(N))
mutualInv(i, j) ≡ ¬ (n[i] = C ∧ n[j] = C)
```

III. CAUSAL RELATIONS AND CONSISTENCY LEMMA

A novel feature of our work lies in that three kinds of causal relations are exploited, which are essentially special cases of the general induction rule. Consider a rule r , a formula f , and a formula set fs , three kinds of causal relations are defined as follows:

Definition 1 We define the following relations:

- 1) $\text{invHoldRule}_1(s, f, r) \equiv s \models \text{pre}(r) \longrightarrow s \models \text{preCond}(f, \text{act}(r));$
- 2) $\text{invHoldRule}_2(s, f, r) \equiv s \models f \longleftrightarrow s \models \text{preCond}(f, \text{act}(r));$
- 3) $\text{invHoldRule}_3(s, f, r, fs) \equiv \exists f' \in fs \text{ s.t. } s \models (f' \wedge (\text{pre}(r)) \longrightarrow s \models \text{preCond}(f, \text{act}(r)));$
- 4) $\text{invHoldRule}(s, f, r, fs) \equiv s \models \text{invHoldRule}_1(s, f, r) \vee s \models \text{invHoldRule}_2(s, f, r) \vee s \models \text{invHoldRule}_3(s, f, r, fs).$

The relation $\text{invHoldRule}(s, f, r, fs)$ defines a causality relation between f , r , and fs , which guarantees that if each formula in fs holds before the execution of rule r , then f holds after the execution of rule r . This includes three cases. 1) $\text{invHoldRule}_1(s, f, r)$ means that after rule r is executed, f becomes true immediately; 2) $\text{invHoldRule}_2(s, f, r)$ states that $\text{preCond}(S, f)$ is equivalent to f , which intuitively means that none of state variables in f is changed, and the execution of statement S does not affect the evaluation of f ; 3) $\text{invHoldRule}_3(s, f, r, fs)$ states that there exists another invariant $f' \in fs$ such that the conjunction of the guard of r and f' implies the precondition $\text{preCond}(S, f)$.

In Hoare logic, a Hoare triple is of the form $\{f\}S\{f'\}$ where f and f' are assertions of formulas and S is a statement. f is named the precondition and f' the postcondition: when the precondition is met, executing S establishes the postcondition.

We can interpret the above three kinds of causality relation in Hoare triples:

- 1) $\text{invHoldRule}_1(s, f, r)$ if and only if $\{\text{pre}(r)\}\text{act}(r)\{f\}$
- 2) $\text{invHoldRule}_2(s, f, r)$ if and only if $\{\text{pre}(r) \wedge f\}\text{act}(r)\{f\}$
- 3) $\text{invHoldRule}_3(s, f, r, fs)$ if and only if $\exists f_0. f' \in fs \wedge (\{\text{pre}(r) \wedge f_0\}\text{act}(r)\{f\})$

$\text{invHoldRule}(s, f, r, fs)$ can be regarded as a special kind of inductive tactics, which can be applied to prove each formula in fs holds at each inductive protocol rule cases.

Lemma 1 Let s and s' be two states and r be a rule s.t. $s \xrightarrow{r} s'$, if $s \models f$ and $\text{invHoldRule}(s, f, r, fs)$ for any $f \in fs$, then for any $f \in fs$, $s' \models f$.

With the invHoldRule relation, we define a consistency relation $\text{consistent}(invs, inis, rs)$ between a protocol $(inis, rs)$ and a set of invariants $invs = \{inv_1, \dots, inv_n\}$.

Definition 2 A relation $\text{consistent}(invs, inis, rs)$ holds if the following conditions hold:

- 1) for all formulas $inv \in invs$ and $ini \in inis$ and all states s , $s \models ini$ implies $s \models inv$;
- 2) for all formulas $inv \in invs$ and rules $r \in rs$ and all states s , $\text{invHoldRule}(s, inv, r, invs)$

Let us use some examples to illustrate the above definitions. Next example gives a set of auxiliary invariants, in which the initially invariant mutualInv is.

Example 2 Let us define

```

invOnXC(i)  $\equiv \neg(x \doteq \text{true} \wedge n[i] \doteq C)$ 
invOnXE(i)  $\equiv \neg(x \doteq \text{true} \wedge n[i] \doteq E)$ 
aux1(i, j)  $\equiv \neg(n[i] \doteq C \wedge n[j] \doteq E)$ 
aux2(i, j)  $\equiv \neg(n[i] \doteq E \wedge n[j] \doteq E)$ 
pinvs(N)  $\equiv \{f. \exists iInv1\ iInv2. iInv1 \leq N \wedge iInv2 \leq N \wedge iInv1 \neq iInv2 \wedge f = \text{mutualInv } iInv1\ iInv2\}$ 
 $\vee (\exists iInv1. iInv1 \leq N \wedge f = \text{invOnXC } iInv1)$ 
 $\vee (\exists iInv1. iInv1 \leq N \wedge f = \text{invOnXE } iInv1)$ 
 $\vee (\exists iInv1\ iInv2. iInv1 \leq N \wedge iInv2 \leq N \wedge iInv1 \neq iInv2 \wedge f = \text{aux1 } iInv1\ iInv2)$ 
 $\vee (\exists iInv1\ iInv2. iInv1 \leq N \wedge iInv2 \leq N \wedge iInv1 \neq iInv2 \wedge f = \text{aux2 } iInv1\ iInv2)$ 

```

In Example 2, $\text{invOnXC}(i)(\text{invOnXE}(i))$ specifies that the variable x will be set to be false once node i is in or exiting the critical section. $\text{aux}_1(i, j)$ says that node i and j can not be in and exiting the critical section at the same time. $\text{aux}_2(i, j)$ that node i and j can not exit critical section at the same time.

Example 3 illustrates the three kinds of causal relations (or inductive tactics).

Example 3 Suppose that $inv = \text{mutual}(i_1, i_2)$, $r = \text{crit}(iR_1)$, $rs = \text{pinvs}(N)$, and $i_1 \leq N$, $i_2 \leq N$, $i_1 \neq i_2$, and $iR_1 \leq N$.

- $\text{invHoldRule}_2(s, inv, r)$, where $i_1 \neq iR_1$, and $i_2 \neq iR_1$, since $\text{preCond}(\text{act}(r), inv) = inv$.
- $\text{invHoldRule}_3(s, inv, r, invs)$, where $i_1 = iR_1$. Since $\text{invOnXC}(i_2) \in invs$, $\text{preCond}(\text{act}(r), inv) = \neg(C =$

$C \wedge n[i_2] = C)$, $\text{invOnXC}(i_2) \wedge \text{pre}(\text{crit}(iR_1)) \longrightarrow \neg n[i_2] = C$, and $s \models \neg n[i_2] = C$ implies $s \models \neg(C = C \wedge n[i_2] = C)$.

- $\text{invHoldRule}_3(s, inv, r, invs)$, where $i_2 = iR_1$. Since $\text{invOnXC}(i_1) \in invs$, $\text{preCond}(\text{act}(r), inv) = \neg(n[i_1] = C \wedge C = C)$, and $\text{invOnXC}(i_1) \wedge \text{pre}(\text{crit}(iR_1)) \longrightarrow \neg n[i_1] = C$, and $s \models \neg n[i_1] = C$ implies $s \models \neg(n[i_1] = C \wedge C = C)$.

Note that checking the above three kinds of causal relations can assisted by a theorem prover, which is the cornerstone of our work.

We can check the consistent relation holds between the auxiliary invariant set example 1 and the protocol initial predicate and rules of the mutual exclusion protocol.

Lemma 2 If $P = (\text{pini}(N), \text{prules}(N))$ is the protocol listed in example 1, and pinvs is the set of formulas in example 2, then $\text{consistent}(\text{pinvs}, \text{pini}(N), \text{prules}(N))$.

Proof: By unfolding the definition of consistency, we need to verify that parts (1) and (2) of the consistency relation hold. For (1), the proof is rather straightforward. We only do case analysis on the form of a formula f in pinvs , and check $\text{pini}(n)$ implies f . For instance, consider the case where $inv = \text{mutualInv}(i_1, i_2)$ for some i_1 and i_2 , where $i_1 \leq N$, $i_2 \leq N$, and $i_1 \neq i_2$. We can conclude that $s \models n[i_2] = I$ if $s \models \text{pini}(N)$, thus $s \models inv$ holds. The other invariants can be proved similarly.

For (2), we do case analysis on the form of a formula f in pinvs , and then on the form of r in $\text{prules}(N)$, notice that both f and r are parameterized, then we do case analysis by comparing indices in f and r , we need show invHoldRule_{1-3} holds. Example 3 has shown a typical case where $inv = \text{mutualInv}(iInv1, iInv2)$, and $r = \text{crit}(iR)$, where $iR \leq N$, $iInv1 \leq N$, and $iInv2 \leq N$. ■

For any invariant $inv \in invs$, inv holds at a reachable state s of a protocol $P = (ini, rs)$ if the consistency relation $\text{consistent}(invs, ini, rs)$ holds. The following lemma formalizes the essence of the aforementioned causal relation, and is called consistency lemma.

Theorem 3 If $P = (ini, rs)$, $\text{consistent}(invs, ini, rs)$, and $s \in \text{reachableSet}(P)$, then for all inv s.t. $inv \in invs$, $s \models inv$.

Now we apply the consistence lemma to prove that the mutual exclusion property holds for each reachable state of the mutual-exclusion protocol. In order to prove the mutual-exclusion property, we prove a more general result:

Lemma 4 If $P = (\text{pini}(N), \text{prules}(N))$ is the protocol listed in example 1, $s \in \text{reachableSet}(P)$, and $0 < N$, and pinvs is the set of formulas in example 2, then for any inv s.t. $inv \in \text{pinvs}(N)$, $s \models inv$.

Proof: By theorem3, we only need to check that parts (1) and (2) of the consistency relation hold. ■

In order to apply the consistency lemma to prove that a given property inv (e.g., the mutual exclusion property) holds for each reachable state of a protocol $P = (inis, rs)$ (e.g., mutual-exclusion protocol), we need to solve two problems. First, we need to construct a set of auxiliary invariants $invs$ which contains inv and satisfies $consistent(invs, inis, rs)$. By applying the consistency lemma, we decompose the original problem of invariant checking into that of checking the causal relation between some $f \in invs$ and $r \in rs$. The latter needs three levels of case analysis: the first is on the form of inv , the second is on r , and the last is on the rule parameters iR and invariant parameters such as i_1 . Only if a proof script contains sufficient information on the case splitting and the kind of causal relation to be checked in each subcase, Isabelle can help us to automatically check it. How to generate automatically such a proof is the second problem.

Fig. 2. The workflow of paraVerifier

Our solutions to the two problems are shown in Fig. 2: Given a protocol, *invFinder* finds all the necessary ground auxiliary invariants from a small instance of the protocol in Murphi. This step solves the first problem. A table *protocol.tbl* is worked out to store the set of ground invariants and causal relations, which are then used by *proofGen* to create an Isabelle proof script which models and verifies the protocol in a parameterized form. In this step, ground invariants are generalized into a parameterized form, and accordingly ground causal relations are adopted to create parameterized proof commands which essentially proves the existence of the parameterized causal relations. This solves the second problem. At last, the Isabelle proof script is fed into Isabelle to check the correctness of the protocol.

IV. SEARCHING AUXILIARY INVARIANTS

Given a protocol \mathcal{P} and a property set F containing invariant formulas we want to verify, *invFinder* in Algorithm 1 aims to find useful auxiliary invariants and causal relations which are capable of proving any element in F . A set A is used to store all the invariants found up to now, and is initialized as F . A queue $newInvs$ is used to store new invariants which have not been checked, and is initialized as F . A relation table $tuples$ is used to record the causal relation between a parameterized rule in some parameter setting and a concrete invariant. Initially $tuples$ is set as NULL. *invFinder* works iteratively in a semi-proving and semi-searching way. In each iteration, the head element f of $newInvs$ is popped, then $Policy(r, f)$ generates groups of parameters $paras$ according to r and f by some policy. For each parameter $para$ in $paras$, it is applied to instantiate r into a concrete rule cr . Here $apply(r, para) = r$ if r contains no array-variables and $para = []$; otherwise $apply(r, para) = r(para_{[1]}, \dots, para_{[|para|]})$. Then $coreFinder(cr, f, A)$ is called to check whether a causal relation exists between cr and f ; if there is such one relation

item, the relation item rel and a formula option $newInvOpt$ is returned; otherwise a run-time error occurs in *coreFinder*, which indicates no proof can be found. In the first case, a tuple $\langle r, para, f, rel \rangle$ will be inserted into $tuples$; If the formula option $newInvOpt$ is NONE, then no new invariant formula is generated; otherwise $newInvOpt = Some(f')$ for some formula f' , then $get(newInvOpt)$ returns f' , and the new invariant formula f' will be pushed into the queue $newInvs$ and inserted into the invariant set A . The above searching process is executed until $newInvs$ becomes empty. At last, the table $tuples$ is returned.

Algorithm 1: Algorithm: *invFinder*

Input: Initially given invariants F , a protocol $\mathcal{P} = \langle I, R \rangle$
Output: A set of tuples which represent causal relations between concrete rules and invariants:

```

1  $A \leftarrow F$ ;
2  $tuples \leftarrow []$ ;
3  $newInvs \leftarrow F$ ;
4 while  $newInvs$  is not empty do
5    $f \leftarrow newInvs.dequeue$ ;
6   for  $r \in R$  do
7      $paras \leftarrow Policy(r, f)$ ;
8     for  $para \in paras$  do
9        $cr \leftarrow apply(r, para)$ ;
10       $newInvOpt, rel \leftarrow coreFinder(cr, f, A)$ ;
11       $tuples \leftarrow tuples @ \langle r, para, f, rel \rangle$ ;
12      if  $newInvOpt \neq NONE$  then
13         $newInv \leftarrow get(newInvOpt)$ ;
14         $newInvs.enqueue(newInv)$ ;
15         $A \leftarrow A \cup \{newInv\}$ ;
16 return  $tuples$ ;

```

In Algorithm 1, the parameter generation policy $Policy$ and the core invariant searching function $coreFinder$ will be illustrated in Section IV-A and IV-B.

A. Parameter Generation Policy

In order to formulate our parameter generation policy, we introduce the concept of permutation modulo to symmetry relation \simeq_m^n , and a quotient set of $perms_m^n$ (the set of all n -permutations of m) under the relation. Here an n -permutation of m is ordered arrangement of an n -element subset of an m -element set $I = \{i.0 < i \leq m\}$. We use a list xs with size n to stand for a n -permutation of m . For instance, $[1, 2]$ is a 2-permutation of 3. $xs[i]$ and $|xs|$ denote the i -th element and the length of xs respectively. If $xs[i] = i$ for all $i \leq |xs|$, we call it identical permutation.

Definition 3 Let m and n be two natural numbers, where $n \leq m$, L and L' are two lists which stand for two n -permutations of m ,

- 1) $L \simeq_m^n L' \equiv (|L| = |L'| = n) \wedge (\forall i. i < |L| \wedge L[i] \leq m - n \longrightarrow L[i] = L'[i])$.
- 2) $L \simeq_m^n L' \equiv L \simeq_m^n L' \wedge L' \simeq_m^n L$.
- 3) $semiP(m, n, S) \equiv (\forall L \in perms_m^n \exists L' \in S. L \simeq_m^n L') \wedge (\forall L \in S. \forall L' \in S. L \neq L' \longrightarrow \neg(L \simeq_m^n L'))$.
- 4) A set S is called a quotient of the set $perms_m^n$ under the relation \simeq_m^n if $semiP(m, n, S)$.

The definition of relation \simeq_m^n (item 1 and 2 in Definition 3) directly leads to the following lemma.

Lemma 5 *If $L \simeq_{m+n}^n L'$, then for any $0 < i \leq |L|$, any $0 < j \leq m$, $L_{[i]} = j$ if and only if $L'_{[i]} = j$.*

For instance, let $L = [2, 3]$ and $L' = [2, 4]$, then $L \simeq_4^2 L'$. Due to Lemma 5, we can analyze a group of concrete parameters by analyzing only one of them as a representative. Keeping this in mind, let us look at the following lemma, which together with Lemma 5 is the theoretical basis of our policy.

Lemma 6 *Let S be a set s.t. $\text{semiP}(m, n, S)$,*

- 1) *for any $L \in \text{perms}_m^n$, there exists a $L' \in S$ s.t. $L \simeq_m^n L'$.*
- 2) *let $L \in S$, $L' \in S$, if $L \neq L'$, then there exists two indice $i \leq m$ and $j \leq n$ such that $L_{[i]} = j$ and $L'_{[i]} \neq j$.*

Lemma 6 shows 1) completeness of S w.r.t. the set perms_m^n under the relation \simeq , 2) the distinction between two different elements in S . Therefore, S has covered all analysing patterns according to the aforementioned comparing scheme between elements of L with numbers $j < n - m$. Moreover, the case patterns represented by different elements in S are different from each other. This fact can be illustrated by the following example.

Example 4 *Let $m = 2$, $n = 1$, $S = \{[1], [2], [3]\}$ and $\text{semiP}(m, n, S)$, let LR be an element in S , there are three cases:*

- 1) $LR = [1]$: *it is a special case where $LR_{[1]} = 1$;*
- 2) $LR = [2]$: *it is a special case where $LR_{[1]} = 2$;*
- 3) $LR = [3]$: *it is a special case where $LR_{[1]} \neq 1$ and $LR_{[1]} \neq 2$.*

Note that the above cases are mutually disjoint, and their disjunction is true.

In Algorithm 1, a concrete formula cinv is popped from the queue newInvs , which can be seen as a normalized instantiation of some parameterized formula pinv .

Definition 4 *A concrete invariant formula cinv is normalized w.r.t a parameterized invariant pinv if there exists no array variable in cinv and $\text{pinv} = \text{cinv}$ or there exists an identical permutation LI with $|LI| > 0$ such that $\text{cinv} = \text{pinv}(1, \dots, |LI|)$;*

Any normalized cinv containing array variables is obtained by instantiating a parameterized invariant pinv with a parameter list which is an identical permutation LI (i.e., the j^{th} parameter is j itself $LI_{[j]} = j$). Thus, consider a list of parameter LR which is used to instantiate a parameterized rule pr , we have $LR_{[i]} = j$ (or $LR_{[i]} \neq j$) is equivalent to $LR_{[i]} = LI_{[j]}$ (or $LR_{[i]} \neq LI_{[j]}$), which is a factor to specify a case by comparing $LR_{[i]}$ with $LI_{[j]}$.

Let cinv be a normalized concrete invariant w.r.t. a parameterized invariant pinv , pr be a parameterized rule, m

be the number of actual parameters occurring in cinv , and n be the number of formal parameters occurring in pr , our policy is to compute a quotient of perms_m^n , denoted as $\text{cmpSemiperm}(m + n, n)$, and use elements of it as a group of parameters to instantiate pr into a set crs of concrete rules, which is shown in Algorithm 2.

Algorithm 2: Computing quotient of perms_m^n :
cmpSemiperm

Input: m, n
Output: A permutation set S

```

1  $S_0 \leftarrow \text{perms}_m^n$ ;
2  $S \leftarrow \emptyset$ ;
3 while  $S_0 \neq \emptyset$  do
4    $L \leftarrow \text{hd}(S_0)$ ;
5    $S_0 \leftarrow \text{tl}(S_0)$ ;
6   if  $\text{find}(\simeq_m^n(L), S) = \text{NONE}$  then
7      $S \leftarrow S @ [L]$ ;
8 return  $S$ ;
```

Algorithm 2 computes a quotient of perms_m^n . Firstly it set $S_0 = \text{perms}_m^n$, then we fetch the head element of S_0 into L , and find whether there is an element L' in S s.t. $L \simeq_m^n L'$. If yes, then L will be discarded, else L is inserted into S . This procedure is repeated until S is empty. For instance, for the invariant $\text{mutuallnv}(1, 2)$, three groups of parameters $[1]$, $[2]$, $[3]$ are used to instantiate crit respectively, each of the instantiation results will be used to check which kind of causal relation exists between it and $\text{mutuallnv}(1, 2)$. Each of the three probed concrete causal relations will be used to generalized into a symbolic causal relation existing between crit and mutuallnv in a case formulated by a predicate comparing rule parameters and invariant parameters.

B. Core Searching Algorithm

For a cinv and a rule $r \in \text{crs}$, the core part of the invFinder tool is shown in Algorithm 3. It needs to call two oracles. The first one, denoted by chk , checks whether a ground formula is an invariant. Such an oracle can be implemented by translating the formula into a formula in SMV, and calling SMV to check whether it is an invariant in a given small reference model of the protocol. If the reference model is too small to check the invariant, then the formula will be checked by Murphi in a big reference model. The second oracle, denoted by tautChk , checks whether a formula is a tautology. Such a tautology checker is implemented by translating the formula into a form in the SMT (SAT Modulo Theories) format, and checking it by an SMT solver such as Z3.

Input parameters of Algorithm ?? include a rule instance r , an invariant inv , a sets of invariants invs . The sets invs stores the auxiliary invariants constructed up to now. The algorithm searches for new invariants and constructs the causal relation between the rule instance r and the invariant inv . The algorithm returns a formula option and a causal relation item between r and inv . A formula option value NONE indicates that no new invariant is found, while $\text{SOME}(f)$ indicates a new auxiliary invariant f is searched.

Algorithm 3: Core Searching Algorithm: *coreFinder*

Input: $r, inv, invs$
Output: A formula option f , a new causal relation rel

```

1  $g \leftarrow$  the guard of  $r$ ,  $S \leftarrow$  the statement of  $r$ ;
2  $inv' \leftarrow \text{preCond}(inv, S)$ ;
3 if  $inv = inv'$  then
4    $relItem \leftarrow (r, inv, invRule_2, -)$ ;
5   return (NONE,  $relItem$ );
6 else if  $\text{tautChk}(g \rightarrow inv') = \text{true}$  then
7    $relItem \leftarrow (r, inv, invRule_1, -)$ ;
8   return (NONE,  $relItem$ );
9 else
10   $candidates \leftarrow \text{subsets}(\text{decompose}(\text{dualNeg}(inv') \wedge g))$ ;
11   $newInv \leftarrow \text{choose}(\text{chk}, candidates)$ ;
12   $relItem \leftarrow (r, inv, invRule_3, newInv)$ ;
13  if  $\text{isNew}(newInv, invs)$  then
14     $newInv \leftarrow \text{normalize}(newInv)$ ;
15    return (SOME( $newInv$ ),  $relItem$ );
16  else
17    return (NONE,  $relItem$ );

```

Algorithm *coreFinder* works as follows: after computing the pre-condition inv' (line 2), which is the weakest precondition of the input formula inv w.r.t. S , the algorithm takes further operations according to the cases it faces with:

- (1) If $inv = inv'$, meaning that statement S does not change inv , then no new invariant is created, and new causal relation item marked with tag $invHoldRule_2$ is recorded between r and inv .
- (2) If tautChk verifies that $g \rightarrow inv'$ is a tautology, then no new invariant is created, and the new causal relation item marked with tag $invHoldRule_1$ is recorded between r and inv .
- (3) If neither of the above two cases holds, then a new auxiliary invariant $newInv$ will be constructed, which will make the causal relation $invHoldRule_3$ to hold. The candidate set is $\text{subsets}(\text{decompose}(\text{dualNeg}(inv') \wedge g))$, where $\text{decompose}(f)$ decompose f into a set of sub-formulas f_i such that each f_i is not of a conjunction form and f is semantically equivalent to $f_1 \wedge f_2 \wedge \dots \wedge f_N$. $\text{dualNeg}(\neg f)$ returns f . $\text{subsets}(S)$ denotes the power set of S . A proper formula is chosen from the candidate set to construct a new invariant $newInv$. This is accomplished by the choose function, which calls the oracle chk to verify whether a formula is an invariant in the given reference model. After $newInv$ is chosen, the function isNew checks whether this invariant is new w.r.t. $newInvs$ or $invs$. If this is the case, the invariant will be normalized, and then be added into $newInvs$, and the new causal relation item marked with tag $invRule_3$ will be added into the causal relations. The meaning of the word “new” is modulo to the symmetry relation. E.g., $\text{mutualInv}(1, 2)$ is equivalent to $\text{mutualInv}(2, 1)$ in a symmetry view.

For instance, let $PC = \{\text{try}, \text{crit}, \text{exit}, \text{idle}\}$, $invs = \{\text{mutualInv}(1, 2)\}$, the output of the *invFinder*, which is

TABLE I
A FRAGMENT OF OUTPUT OF *invFinder*

rule	ruleParas	inv	causal relation	f'
..
crit	[1]	mutualInv(1,2)	invHoldRule3	invOnXC(2)
crit	[2]	mutualInv(1,2)	invHoldRule3	invOnXC(1)
crit	[3]	mutualInv(1,2)	invHoldRule2	
..
crit	[1]	invOnXC(1)	invHoldRule1	
crit	[2]	invOnXC(1)	invHoldRule1	

stored in file `mutual.tbl`, is shown in Table I. In the table, each line records the index of a normalized invariant, name of a parameterized rule, the rule parameters to instantiate the rule, a causal relation between the ground invariant and a kind of causal relation which involves the kind and proper formulas f' in need (which are used to construct causal relations invHoldRule_3). The auxiliary invariants found by *invFinder* include: $inv_2 \equiv \neg(x = \text{true} \wedge n[1] = C)$, $inv_3 \equiv \neg(n[1] = C \wedge n[2] = E)$, $inv_4 \equiv \neg(x = \text{true} \wedge n[1] = E)$, $inv_5 \equiv \neg(n[1] = E \wedge n[2] = E)$.¹

V. GENERALIZATION

Intuitively, generalization means that a concrete index (formula or rule) is generalized into a set of concrete indices (formulas or rules), which can be formalized by a symbolic index (formula or rules) with side conditions specified by constraint formulas. In order to do this, we adopt a new constructor to model symbolic index or symbolic value $\text{symb}(str)$, where str is a string. We use N to denote $\text{symb}("N")$, which formalizes the size of an parameterized protocol instance. A concrete index i can be transformed into a symbolic one by some special strategy g , namely $\text{symbolize}(g, i) = \text{symb}(g(i))$. In this work, two special transforming function $\text{flnv}(i) = "iInv" \wedge \text{itoa}(i)$ and $\text{flr}(i) = "iR" \wedge \text{itoa}(i)$, where $\text{itoa}(i)$ is the standard function transforming an integer i into a string. We use special symbols $iInv_i$ to denote $\text{symbolize}(fInv, i)$; and iR_i to denote $\text{symbolize}(fIr, i)$. The former formalizes a symbolic parameter of a parameterized formula, and the latter a symbolic parameter of a parameterized rule. Accordingly, we define $\text{symbolize2f}(g, inv)$ (or $\text{symbolize2r}(g, r)$), which returns the symbolic transformation result to a concrete formula inv (or rule r) by replacing a concrete index i occurring in inv (or r) with a symbolic index $\text{symbolize}(g, i)$.

There are two main kinds of generalization in our work: (1) generalization of a normalized invariant into a symbolic one. The resulting symbolic invariants are used to create definitions of invariant formulas in Isabelle. For instance, $\neg(x \doteq \text{true} \wedge n[1] \doteq C)$ is generalized into $\neg(x \doteq \text{true} \wedge n[iInv_1] \doteq C)$. This kind of generalization is done with model constraints, which specify that any parameter index should be not greater than the instance size N , and parameters to instantiate a parameterized rule (formula) should be different. (2) The generalization of concrete causal relations into parameterized causal relations in

¹The names `mutualEx` and `invOnX1` in this work are just for easy-reading, their index here is generated in some order by *invFinder*

Isabelle, and will be used in proofs of the existence of causal relations in Isabelle.

Since the first kind of generalization is simple, we focus on the second kind of generalization, which consists of two phases. Firstly, groups of rule parameters such as $[[1],[2],[3]]$ will be generalized into a list of symbolic formulas such as $[iR_1 = iInv_1, iR_1 = iInv_2, (iR_1 \neq iInv_1) \wedge (iR_1 \neq iInv_2)]^2$, which stands for case-splittings by comparing a symbolic rule parameter iR_1 and invariant parameters $iInv_1$ and $iInv_2$. In the second phase, the formula field accompanied with a $invHoldRule3$ relation is also generalized by some special strategy.

Now let us look at the first phase, starting with some definitions. Consider a line of concrete causal relation shown in Table I, there is a group of rule parameters LR , and a group of parameters LI occurring in an invariant formula.

Definition 5 Let LR be a permutation s.t. $|LR| > 0$, which represents a list of actual parameters to instantiate a parameterized rule, let LI be a permutation $|LI| > 0$, which represents a list of actual parameters to instantiate a parameterized invariant, we define:

- 1) symbolic comparison condition generalized from comparing $LR_{[i]}$ and $LI_{[j]}$:
 $\text{symbCmp}(LR, LI, i, j) \equiv$

$$\begin{cases} iR_i = iInv_j & \text{if } LR_{[i]} = LI_{[j]} \\ iR_i \neq iInv_j & \text{otherwise} \end{cases} \quad (1)$$

- 2) symbolic comparison condition generalized from comparing $LR_{[i]}$ and with all $LI_{[j]}$:
 $\text{symbCaseI}(LR, LI, i) \equiv$

$$\begin{cases} \text{symbCmp}(LR, LI, i, j) & \text{if } \exists! j. LR_{[i]} = LI_{[j]} \\ \text{forallForm}(|LI|, pf) & \text{otherwise} \end{cases} \quad (2)$$

where $pf(j) = \text{symbCmp}(LR, LI, i, j)$, and $\exists! j.P$ is an qualifier meaning that there exists a unique j s.t. property P ;

- 3) symbolic case generalized from comparing LR with LI :
 $\text{symbCase}(LR, LI) \equiv \text{forallForm}(|LR|, pf)$, where $pf(i) = \text{symbCaseI}(LR, LI, i)$;
- 4) symbolic partition generalized from comparing all $LR_{[k]}$ with LI , where LR is a list of permutations with the same length:
 $\text{partition}(LR, LI) \equiv \text{existsForm}(|LR|, pf)$, where $pf(i) = \text{symbCase}(LR, LI, i)$.

$\text{symbCmp}(LR, LI, i, j)$ defines a symbolic formula generalized from comparing $LR_{[i]}$ and $LI_{[j]}$; $\text{symbCaseI}(LR, LI, i)$ a symbolic formula summarizing the results of comparison between $LR_{[i]}$ and all $LI_{[j]}$ such that $j \leq |LI|$; $\text{symbCase}(LR, LI)$ a symbolic formula representing a subcase generalized from comparing all $LR_{[i]}$ and all $LI_{[j]}$; $\text{partition}(LR, LI)$ is a disjunction of subcases $\text{symbCase}(LR_{[i]}, LI)$. Recall the first three lines in Table I, and $LI = [1, 2]$ is the list of parameters occurring in

$\text{mutualEx}(1, 2)$; and LR is the actual parameter list to instantiate crit .

- when $LR = [1]$, $\text{symbCmp}(LR, LI, 1, 1) = (iR_1 = iInv_1)$, $\text{symbCase}(LR, LI) = \text{symbCaseI}(LR, LI, 1) = (iR_1 = iInv_1)$ because $LR_{[1]} = LI_{[1]}$.
- when $LR = [2]$, $\text{symbCmp}(LR, LI, 1, 2) = (iR_1 = iInv_2)$, $\text{symbCase}(LR, LI) = \text{symbCaseI}(LR, LI, 2) = (iR_1 = iInv_2)$ because $LR_{[1]} = LI_{[2]}$.
- when $LR = [3]$, $\text{symbCmp}(LR, LI, 1, 1) = (iR_1 \neq iInv_1)$, $\text{symbCmp}(LR, LI, 1, 2) = (iR_1 \neq iInv_2)$, $\text{symbCase}(LR, LI) = \text{symbCaseI}(LR, LI, 1) = (iR_1 \neq iInv_1) \wedge (iR_1 \neq iInv_2)$ because neither $LR_{[1]} = LI_{[1]}$ nor $LR_{[1]} = LI_{[2]}$.
- let $LR = [[1], [2], [3]]$, $\text{partition}(LR, LI) = (iR_1 = iInv_1) \vee (iR_1 = iInv_2) \vee ((iR_1 \neq iInv_1) \wedge (iR_1 \neq iInv_2))$

If we see a line in table I as a concrete test case for some concrete causal relation, then $\text{symbCase}(LR, LI)$ is an abstraction predicate to generalize the concrete case. Namely, if we transform $\text{symbCase}(LR, LI)$ by substituting $iInv_i$ with $LI_{[i]}$, and iR_j with $LR_{[j]}$, the result is semantically equivalent to true.

The second phase of generalization of concrete causal relations is to generalize the formula inv' accompanied with a causal relation $invHoldRule3$ in a line of table I. An index occurring in f' can either occur in the invariant formula, or in the rule. We need to look it up to determine the transformation.

Definition 6 Let LI and LR are two permutations, $\text{find_first}(L, i)$ returns the least index j s.t. $L_{[j]} = i$ if there exists such an index; otherwise returns an error.

$$\text{lookup}(LI, LR, i) \equiv \begin{cases} iInv_{\text{find_first}(LI, i)} & \text{if } i \in LI \\ iR_{\text{find_first}(LR, i)} & \text{otherwise} \end{cases} \quad (3)$$

$\text{lookup}(LI, LR, i)$ returns the symbolic index transformed from i according to whether i occurs in LI or in LR . The index i will be transformed into $iInv_{\text{find_first}(LI, i)}$ if i occurs in LI , and $iR_{\text{find_first}(LR, i)}$ otherwise. Employing the lookup strategy to transform a concrete index i in inv' to $\text{lookup}(LI, LR, i)$, symbolize2f transforms inv' into a symbolic one which will be needed in a proof command for existence of the $invHoldRule3$ relation in Isabelle.

VI. AUTOMATICAL GENERATION OF ISABELLE PROOF

A formal model for a protocol case in a theorem prover like Isabelle includes the definitions of constants and rules and invariants, lemmas, and proofs. Readers can refer to [12] for detailed illustration of the formal proof script. In this section, we focus on the generation of a lemma on the existence of causal relation between a parameterize rule and invariant formula based on the aforementioned generalization of lines of concrete causal relations.

An example lemma critVsinv_1 and its proof in Isabelle in the mutualEx protocol, is illustrated as follows:

² $iR_1 \neq iInv_1$ is the abbreviation of $!(iR_1 = iInv_1)$

```

1 lemma critVsinv1:
2   assumes a1:  $\exists iR1. iR1 \leq N \wedge r = \text{crit } iR1$  and
3   a2:  $\exists iInv1\ iInv2. iInv1 \leq N \wedge iInv2 \leq N \wedge iInv1 \neq iInv2$ 
4    $\wedge f = \text{inv1 } iInv1\ iInv2$ 
5   shows  $\text{invHoldRule } s\ f\ r\ (\text{invariants } N)$ 
6   proof -
7     from a1 obtain iR1 where a1:  $iR1 \leq N \wedge r = \text{crit } iR1$ 
8     by blast
9     from a2 obtain iInv1 iInv2 where a2:  $iInv1 \leq N$ 
10     $\wedge iInv2 \leq N \wedge iInv1 \neq iInv2 \wedge f = \text{inv1 } iInv1\ iInv2$ 
11    by blast
12  have  $iR1 = iInv1 \vee iR1 = iInv2 \vee (iR1 \neq iInv1 \wedge iR1 \neq iInv2)$ 
13  by auto
14  moreover { assume b1:  $iR1 = iInv1$ 
15    have  $\text{invHoldRule3 } s\ f\ r\ (\text{invariants } N)$ 
16    proof (cut_tac a1 a2 b1, simp,
17      rule_tac x =  $\neg (x = \text{true} \wedge n[iInv2] = C)$  in exI, auto) qed
18    then have  $\text{invHoldRule } s\ f\ r\ (\text{invariants } N)$  by auto }
19  moreover { assume b1:  $iR1 = iInv2$ 
20    have  $\text{invHoldRule3 } s\ f\ r\ (\text{invariants } N)$ 
21    proof (cut_tac a1 a2 b1, simp,
22      rule_tac x =  $\neg (x = \text{true} \wedge n[iInv1] = C)$  in exI, auto) qed
23    then have  $\text{invHoldRule } s\ f\ r\ (\text{invariants } N)$  by auto }
24  moreover { assume b1:  $iR1 \neq iInv1 \wedge iR1 \neq iInv2$ 
25    have  $\text{invHoldRule2 } s\ f\ r$ 
26    proof (cut_tac a1 a2 b1, auto) qed
27    then have  $\text{invHoldRule } s\ f\ r\ (\text{invariants } N)$  by auto }
28  ultimately show  $\text{invHoldRule } s\ f\ r\ (\text{invariants } N)$  by blast
29 qed

```

In the above proof, line 2 are assumptions on the parameters of the invariant and rule, which are composed of two parts: (1) assumption a1 specifies that there exists an actual parameter $iR1$ with which r is a rule obtained by instantiating crit ; (2) assumption a2 specifies that there exists actual parameters $iInv1$ and $iInv2$ with which f is a formula obtained by instantiating inv1 . Line 4 are two typical proof patterns forward-style which fixes local variables such as $iR1$ and new facts such as $a1: iR1 \leq N \wedge r = \text{crit } iR1$. From line 5, the remaining part is a typically readable Isar proof using calculation reasoning such as `moreover` and ultimately to do case analysis. Line 5 splits cases of $iR1$ into all possible cases by comparing $iR1$ with $iInv1$ and $iInv2$, which is in fact characterized by partition($[1], [2], [3], [1, 2]$). Lines 6-14 proves these cases one by one: Lines 6-8 proves the case where $iR1 = iInv1$, line 7 first proves that the causal relation invHoldRule_3 holds by supplying a symbolic formula, which is transformed from $\text{invOnXC}(2)$ by calling `symbolize2f` with `lookUp` strategy. From the conclusion at line 7, line 8 furthermore proves the causal relation invHoldRule holds; Lines 9-11 proves the case where $iR1 = iInv2$, proof of which is similar to that of case 1; Lines 12-14 the case where neither $iR1 = iInv1$ nor $iR1 = iInv2$. Each proof of a subcase is done in a block `moreover b1: asml proof1`, the ultimately proof command in line 15 concludes by summing up all the subcases.

With the help of all the lemmas such as `ruleVsinv1`, we can prove the following lemma `lemma_inv_1_on_rules` which specifies that for all $r \in \text{rules } N$, and f is a formula f which is generated by instantiating inv1 with some parameters $iInv1$ and $iInv2$, $\text{invHoldForRule } s\ f\ r\ (\text{invariants } N)$.

```

1 lemma lemma_inv1_on_rules:
2   assumes a1:  $r \in \text{rules } N$  and
3   a2:  $(\exists iInv1\ iInv2. iInv1 \leq N \wedge iInv2 \leq N \wedge iInv1 \neq iInv2 \wedge f = \text{inv1 } iInv1\ iInv2)$ 
4   shows  $\text{invHoldForRule } s\ f\ r\ (\text{invariants } N)$ 
5   proof -
6     have  $(\exists i. i \leq N \wedge r = \text{try } i) \vee (\exists i. i \leq N \wedge r = \text{crit } i) \vee (\exists i. i \leq N \wedge r = \text{exit } i) \vee (\exists i. i \leq N \wedge r = \text{idle } i)$ 
7     apply (cut_tac a1, auto) done
8   moreover { assume b1:  $(\exists i. i \leq N \wedge r = \text{try } i)$ 
9     have  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
10    apply (cut_tac a2 b1, metis tryVsinv1) done }
11  moreover { assume a1:  $(\exists i. i \leq N \wedge r = \text{crit } i)$ 
12    have  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
13    apply (cut_tac a2 b1, metis critVsinv1) done }
14  moreover { assume a1:  $(\exists i. i \leq N \wedge r = \text{exit } i)$ 
15    have  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
16    apply (cut_tac a2 b1, metis exitVsinv1) done }
17  moreover { assume a1:  $(\exists i. i \leq N \wedge r = \text{idle } i)$ 
18    have  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
19    apply (cut_tac a2 b1, metis idleVsinv1) done }
20  ultimately show  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
21  by auto
22  qed

```

With the help of all the lemmas such as `lemma_invi_on_rules`, we can prove the following lemma `invs_on_rules` which specifies that for all $f \in \text{invariants } N$ and $r \in \text{rules } N$, $\text{invHoldForRule } s\ f\ r\ (\text{invariants } N)$.

```

1 lemma invs_on_rules: assumes a1:  $f \in \text{invariants } N$ 
2   and a2:  $r \in \text{rules } N$ 
3   shows  $\text{invHoldForRule}'\ s\ f\ r\ (\text{invariants } N)$ 
4   proof -

1) Lemmas on initial states: In this section, we discuss the definition on the initial state of the protocol, and the lemmas specifying that each invariant formula holds at the initial state.

A typical Isabelle definition on the initial state of the protocol is as follows:

```

definition initSpec0::nat  $\Rightarrow$  formula where [simp]:
initSpec0 N  $\equiv$  (forallForm (down N)
(% i . (eqn (IVar (Para (Ident "'n'") i)) (Const I))))
definition initSpec1::formula where [simp]:
initSpec1  $\equiv$  (eqn (IVar (Ident "'x'")) (Const true))
definition allInitSpecs::nat  $\rightarrow$  formula list
allInitSpecs N  $\equiv$  [(initSpec0 N), (initSpec1)]
lemma iniImplInv4:
assumes a1: ( $\exists$  iInv1. iInv1  $\leq$  N  $\wedge$  f = inv4 iInv1)
and a2: formEval (andList (allInitSpecs N)) s
shows formEval f s
using a1 a2 by auto

```

initSpec0 and initSpec1 specifies the assignments on each variable $n[i]$ where $i \leq N$ and x . The specifications of the initial state is the list of all the specification definition on related state variables. Lemma iniImplInv4 simply specifies that the invariant formula $inv4$ holds at a state s which satisfies the conjunction of the specification of the initial state. Isabelle's auto method can solve this goal automatically. Other lemmas specifying that other invariant formulas hold at the initial state are similar.

With the lemmas such as iniImplInv4, for any invariant $inv \in (\text{invariants } N)$, any state s , if ini is evaluated true at state s , then inv is evaluated true at state s .

```

lemma on_inis: assumes a1: f  $\in$  (invariants N)
and a2: ini  $\in$  { andList (allInitSpecs N) }
and a3: formEval ini s
shows formEval f s
proof -
have c1: ( $\exists$  iInv1 iInv2. iInv1  $\leq$  N  $\wedge$  iInv2  $\leq$  N  $\wedge$  iInv1  $\neq$  iInv2

ultimately show formEval f s by auto
qed

```

The proof structure of lemma_inv1_on_rules and invs_on_rules and on_inis are also typical case analysis ones using moreover blocks and ultimately commands, therefore, a generic program of generating a typical case analysis proof

will be adopted in our framework.

2) *The main theorem:* With the preparation of lemma on_inis and invs_on_rules, the generation of the main lemma is quite easy. Recall that the consistency lemma is our main weapon to prove the main lemma, which requires proving two parts of obligations.

- (1) For any invariant $inv \in (\text{invariants } N)$, any state s , if ini is evaluated true at state s , then inv is evaluated true at state s . This can be solved done by applying lemma on_inis.
- (2) For any invariant $inv \in (\text{invariants } N)$, any r in rule set rules N , one of the causal relations $invHoldForRule_{1-3}$ holds. This can be solved done by applying lemma invs_on_rules.

```

```

The generation of the main lemma is quite easy because it is in a standard form.

A. Algorithms of Proof Generator proofGen

In this subsection, we illustrate the key techniques and algorithms of generation of the lemmas and their proofs in subsection ???. Being according with the order in which we introduce the above lemmas, we also introduce their generation in a bottom-up order. First let us introduce the generation of a subproof according to a relation tag of $invHoldForRule_{1-3}$, which is shown in Algorithm 11.

In the body of function rel2proof, *sprintf* writes a formatted data to string and returns it. In line 10, *getFormField(relTag)* returns f' if $relTag = invHoldForRule_3(f')$. rel2proof transforms a relation tag into a paragraph of proof. If the tag is among $invHoldForRule_{1-2}$, the transformation is rather straight-forward, else the form f' is assigned by the formula *getFormField(relTag)*, and provided to tell Isabelle the formula which should be used to construct the $invHoldForRule_3$ relation.

Algorithm 4: Generating a kind of proof which is according with a relation tag of *invHoldForRule₁₋₃* : *rel2proof*

Input: A causal relation item *relTag*
Output: An Isabelle proof: *proof*

```

1 if relTag = invHoldForRule1 then
2   proof ← sprintf
3   "have invHoldForRule1 f r (invariants N)
4   by(cut_tac a1 a2 b1, simp, auto)
5   then have invHoldForRule f r (invariants N) by blast" ;
6 else if relTag = invHoldForRule2 then
7   proof ← sprintf
8   "have invHoldForRule2 f r (invariants N) by(cut_tac a1
9   a2 b1, simp, auto)
10  then have invHoldForRule f r (invariants N) by blast" ;
11 else
12   f' ← getFormField(relTag);
13   proof ← sprintf
14   "have invHoldForRule3 f r (invariants N)
15   proof(cut_tac a1 a2 b1, simp, rule_tac x=%s in
16   exI,auto)qed
17   then have invHoldForRule f r (invariants N) by blast"
18   (sympb2Isabelle f');
19 return proof

```

Algorithm 5: Generating one sub-proof for a subcase: *oneMoreOverGen*

Input: A formula *caseFsm* standing for the assumption of the subcase, a relation item *relItem* containing the information of causal relation
Output: An Isabelle proof: *subProof*

```

1 proof ← rel2proof(relItem);
2 subProof ← sprintf
3 "moreover{assume b1:%s
4 %s } "
5 (asm, proof);
6 return subProof

```

In Algorithm 5, *oneMoreOverGen* generates a subproof for a subcase in a proof of case analysis. It returns a subproof which is composed by filling an assumption of the subcase such as "*iR1=IInv1*" and a paragraph of proof generated by *rel2proof*(*relItem*) into a format of block *moreover* { ... }.

Due to the common use of case analysis proof of using *moreover* and *ultimately* commands, we design a generic program of generating doing case analysis *doCaseAnalz*. In algorithm 6, formulas standing for case-splitting *partition*, subproofs *subproofs*, and the conclusion *concluding* are needed in case analysis to fill the format.

In algorithm 7, *caseAnalzI* generates a typical proof of doing case analysis to prove some causal relation hold between some rule and invariant. *oneMoreOverGenI*(*case*,*rel*) formula comes from the disjunction of formulas in the *sympCases* field of *rec*, which is returned by *caseField*(*rec*), subproofs *subproofs* are generated by concatenation of all the subproofs, each of which is generated by *oneMoreOverGenI*(*case*,*rel*). The proof is simply composed by calling *doCaseAnalz*(*partition*, *subproofs*, *concluding*).

Algorithm 6: Generating a whole proof of doing case analysis: *doCaseAnalz*

Input: A formula *partition* standing for case-splittings, a proof list *subproofs* standing all the subproofs of each subcases, concluding parts *concluding*
Output: An Isabelle proof: *proof*

```

1 proof ← sprintf
2 " have %s by auto
3 %s
4 ultimately show %s by auto"
5 (partition, subproofs, concluding) ;
6 return proof

```

Algorithm 7: Generating a whole proof of doing case analysis on parameters of rule and invariant: *caseAnalzI*

Input: A record *rec* fetched from *sympCausal*
Output: An Isabelle proof: *proof*

```

1 cases ← caseField(rec);
2 rels ← relItems(rec); partition ←  $\bigvee$  cases;
3 subproofs ← "";
4 while (cases ≠ []) do
5   case ← hd(cases) ;
6   cases ← tl(cases) ;
7   rel ← hd(rels) ;
8   rels ← tl(rels) ;
9   subproofs ←
10  subproofs ^ oneMoreOverGenI(case, rel);
11 concluding ← "invHoldForRule s f r (invariants N) ";
12 proof ← doCaseAnalz(partition, subproofs, concluding);
13 return proof

```

Next we discuss how to generate assumptions on an invariant formula of an lemma such as *critVsInv1*. In the body of algorithm 8, *tbl_element*(*sympInvs*, *invName*) retrieves the record on a invariant formula from *sympInvs* to *invItem* by its name *invName*, *invParaNum*(*invItem*) and *constrOfInv*(*invItem*) return the field *invNumFld* and *constr* of *invItem* respectively. *invParasGen*(*lenPIInv*) generates a string of a list of actual parameters such as *iInv1...iInv_{lenPIInv}* if *lenPIInv* > 0, else an empty string "". At last, the assumption on the invariant is created by filling *invParas*, *constrOnInv*, and *invName* into a proper place in the format if needed.

Similar to *asmGenOnInv*, *obtainGenOnInv*, which is shown in algorithm 9, generates a proof command of *obtain* by retrieving and generating the related information and filling them in a format on *obtain*. Similar to *asmGenOnInv* and *obtainGenOnInv*, *asmGenOnRule* and *obtainGenOnRule* generate an assumption and *obtain* proof command on a rule.

After the above preparing functions, now the generation of a lemma on the causal relation such as *critVsInv1* is rather easy, which is shown in algorithm 10. After generating an assumption on invariant formula *asm1*, *asm2* on a rule, an *obtain* command *obtain1* on the invariant, and *obtain2* on the rule, *symRelItem* is retrieved from *symCausalTab* by *ruleName* ^ *invName*, and a proof *proof* is generated by calling *caseAnalzI*(*symRelItem*). At last these parts are filled into proper places in the lemma format.

Algorithm 8: Generating an assumption on an invariant formula: `asmGenOnInv`

Input: An invariant name *invName*, a table *symInvs* storing invariant formulas

Output: An assumption on an invariant formula: *asm*

```

1 invItem  $\leftarrow$  tbl_element(symbInvs, invName);
2 lenPInv  $\leftarrow$  invParaNum(invItem);
3 invParas  $\leftarrow$  invParasGen(lenPInv);
4 constrOnInv  $\leftarrow$ 
  sybForm2Isabelle(constrOfInv(invItem));
5 if lenPInv = 0 then
6   asm  $\leftarrow$  "a1 : f = " ^ invName;
7 else
8   asm  $\leftarrow$  sprintf "a1 :  $\exists$  %s. %s  $\wedge$  f=%s %s" (invParas,
    constrOnInv, invName, invParas);
9 return asm

```

Algorithm 9: Generating an obtain proof command on an invariant formula: `obtainGenOnInv`

Input: An invariant name *invName*, a table *symInvs* storing rules

```

1 invItem  $\leftarrow$  tbl_element(symbInvs, invName);
2 lenPInv  $\leftarrow$  invParaNum(invItem);
3 invParas  $\leftarrow$  invParasGen(lenPInv);
4 if lenPInv = 0 then
5   obtain  $\leftarrow$  "";
6 else
7   obtain  $\leftarrow$  sprintf "from a1 obtain %s where a1:%s  $\wedge$  f=%s
    %s by auto"
    (invParas, constrOnInv, invName, invParas);
8
9 return obtain

```

Algorithm 10: Generating a lemma on a causal relation: `lemmaOnCausalRuleInv`

Input: A parameterized rule name *ruleName*, a formula name *invName*, a table *symRules* storing rules, a table *symInvs* storing invariant formulas, a table *symCausalTab* storing causal relation

Output: An Isabelle proof script for a lemma: *lemmaWithProof*

```

1 asm1  $\leftarrow$  asmGenOnInv(symbInvs, invName);
2 asm2  $\leftarrow$  asmGenOnRule(symbRules, ruleName);
3 obtain1  $\leftarrow$  obtainGenOnInv(symbInvs, invName);
4 obtain2  $\leftarrow$  obtainGenOnRule(symbRules, ruleName);
5 symRelItem  $\leftarrow$ 
  tbl_element(symCausalTab, (ruleName ^ invName));
6 proof  $\leftarrow$  caseAnalzI(symRelItem);
7 lemmaWithProof  $\leftarrow$  sprintf
8   "lemma %sVs%s:
9   assumes %s and %s
10  shows invHoldForRule s f r (invariants N)
11  proof - %s %s %s
12  qed"
13  (ruleName, invName, asm1, asm2, obtain1, obtain2, proof)
14 return lemmaWithProof

```

Due to length limitation, we illustrate the algorithm for generating a key part of the proof of the lemma `critVsinvl`: the generation of a subproof (e.g., lines 7-8) according to a symbolic relation tag of *invHoldRule*₁₋₃, which is shown in Algorithm 11. Input *relTag* is the result of the generalization step, which is discussed in Section V. In the body of function

Algorithm 11: Generating a kind of proof which is according with a relation tag of *invHoldRule*₁₋₃ : `rel2proof`

Input: A symbolic causal relation item *relTag*

Output: An Isabelle proof: *proof*

```

1 if relTag = invHoldRule1 then
2   proof  $\leftarrow$  sprintf
3     "have invHoldRule1 f r (invariants N)
4     by(cut_tac a1 a2 b1, simp, auto)
5     then have invHoldRule f r (invariants N) by blast" ;
6 else if relTag = invHoldRule2 then
7   proof  $\leftarrow$  sprintf
8     "have invHoldRule2 f r (invariants N) by(cut_tac a1 a2
9     b1, simp, auto)
    then have invHoldRule f r (invariants N) by blast" ;
10 else
11   f'  $\leftarrow$  getFormField(relTag);
12   proof  $\leftarrow$  sprintf
13     "have invHoldRule3 f r (invariants N)
14     proof(cut_tac a1 a2 b1, simp, rule_tac x=%s in
15     exI,auto)qed
    then have invHoldRule f r (invariants N) by blast"
    (sybForm2Isabelle f');
16 return proof

```

`rel2proof`, `sprintf` writes a formatted data to string and returns it. In line 10, `getFormField(relTag)` returns the field of formula *f'* if *relTag* = *invHoldRule*₃(*f'*). `rel2proof` transforms a symbolic relation tag into a paragraph of proof, as shown in lines 7-8, 10-11, or 13-14. If the tag is among *invHoldRule*₁₋₂, the transformation is rather straight-forward, else the form *f'* is assigned by the formula `getFormField(relTag)`, and provided to tell Isabelle the formula which is used to construct the *invHoldRule*₃ relation.

VII. EXPERIMENTS

We implement our tool in Ocaml. Experiments are done with typical bus-snoopy benchmarks such as MESI and MOESI, as well as directory-based benchmarks such as German and FLASH. The detailed codes and experiment data can be found in [12]. Each experiment data includes the `paraVerifier` instance, invariant sets, Isabelle proof scripts. Experiment results are summarized in Table II.

Among all the work in the field of parameterized verification, only four of them have verified FLASH. The first full verification of safety properties of FLASH is done in [10]. Park and Dill proved the safety properties of FLASH using PVS. The CMP method, which adopts parameter abstraction and guard strengthening, is applied in [6] for verifying safety properties of FLASH. McMillan applied compositional model checking [11] and used Candence SMV to the verification of both safety and liveness properties of FLASH. Sylvain

TABLE II
VERIFICATION RESULTS ON BENCHMARKS.

Protocols	#rules	#invariants	time (seconds)	Memory (MB)
mutualEx	4	5	3.25	7.3
MESI	4	3	2.47	11.5
MOESI	5	3	2.49	23.2
Germanish [9]	6	3	2.9	7.8
German [6]	13	52	38.67	14
FLASH_nodata	60	152	280	26
FLASH_data	62	162	510	26

et.al have applied Cubeic to the verification FLASH [9], [13], which is theoretically based on an SMT model checking to the verification of array-based system. In the former three methods [10], [6], [11], auxiliary invariants are provided manually depending on verifier's deep insight in the FLASH protocol itself, while in Cubeic, auxiliary invariants are found automatically. In Cubeic, auxiliary invariants are searched backward by a heuristics-guided algorithm with the help of an oracle (a reference instance of the protocol), but these auxiliary invariants are in concrete form, and are not generalized to the parameterized form. Thus there is no parameterized proof derived for parameterized verification of FLASH.

The invariants-searching algorithm used in our work differs from that in Cubeic [9], [13] in that the heuristics in our work are based on the construction of causal relation which is uniquely proposed in our work. Thus the auxiliary invariants in our work are different from those found in [9], [13]. Moreover, we generalize these concrete invariants and causal relations into a parameterized proof, and generate a parameterized proof in Isabelle. The found invariants have abundant semantics reflecting the deep insight of the FLASH protocol design, and the readable Isabelle proof script formally proves these invariants. In this way, we prove the protocol with the highest assurance. To the best of knowledge, this work for the first time automatically generates a proof of safety properties of full version of FLASH in a theorem prover without auxiliary invariants manually provided by people.

VIII. CONCLUSION

The originality of paraVerifier lies in the following aspects: (1) instead of directly proving the invariants of a protocol by induction, we propose a general proof method based on the consistency lemma to decompose the proof goal into a number of small ones; (2) instead of proving the decomposed subgoals by hand, we automatically generate proofs for them based on the information of causal relation computed in a small protocol instance.

As we demonstrate in this work, combining theorem proving with automatic proof generation is promising in the field of formal verification of industrial protocols. Theorem proving can guarantee the rigorousness of the verification results, while automatic proof generation can release the burden of human interaction.
